

THE BLIND SPOT

Problem Statement

People often make decisions based on the information that is most visible to them. In the process, they may overlook important factors, rely on unstated assumptions, or fail to recognize conflicts within their own reasoning.

These overlooked elements can significantly affect how a decision is understood and evaluated.

Challenge

Build an **AI-powered solution that helps users identify potential blind spots in their reasoning when considering a decision.**

The solution should encourage users to examine their assumptions, recognize what they may have overlooked, and explore questions that could lead to a more informed decision.

The system **should not make the decision for the user**. Its purpose is to help the user think more critically about the decision.

Example

A student is deciding whether to accept a 6-month internship. They provide details about the stipend, location, working hours, role, learning opportunities, and their college schedule. They explain that they are mainly considering it because the stipend is good, the company is close to home, and it will provide industry experience.

The AI should analyze the student's reasoning and help them recognize aspects they may have overlooked, such as the impact on academics, actual learning and mentorship opportunities, and long-term career prospects, while also questioning assumptions that may affect their decision.

The AI should help the student think more critically about the decision without deciding for them.

Constraints

- **3 hours** to build the solution.
- The solution must be **deployed** and accessible through a working link.
- No organizer-provided dataset will be provided.

- Participants may choose their own technology stack and implementation approach.
- The solution should demonstrate meaningful use of AI.

Submission

Participants must submit:

- Working deployed application
- GitHub repository
- Brief description of the solution
